QuestionAnswer What is the primary difference between gram-positive and gram-negative bacteria in microbiology? Gram-positive bacteria have a thick peptidoglycan layer in their cell wall that retains the crystal violet stain, appearing purple under a microscope. In contrast, gram-negative bacteria have a thinner peptidoglycan layer and an outer membrane, which does not retain the crystal violet stain and appears pink after counterstaining with safranin. Which microorganism is the causative agent of tuberculosis? *Mycobacterium tuberculosis* is the causative agent of tuberculosis. What is the function of bacterial endospores? Bacterial endospores are highly resistant dormant structures that allow bacteria to survive extreme environmental conditions such as heat, desiccation, chemicals, and radiation, ensuring their survival until conditions become favorable again. Which staining technique is commonly used to identify *Mycobacteria*? The Ziehl-Neelsen acid-fast stain is commonly used to identify *Mycobacteria* due to their acid-fast cell wall properties. What role do biofilms play in microbiology? Biofilms are communities of microorganisms encased in a self-produced extracellular matrix that adhere to surfaces. They protect microorganisms from environmental stresses, antibiotics, and the host immune response, contributing to persistent infections.
