Question What are the main components of a typical plant cell involved in plant anatomy? The main components include the cell wall, cell membrane, cytoplasm, nucleus, vacuole, chloroplasts, and mitochondria, which collectively contribute to the plant's structure and function. Describe the differences between xylem and phloem in plant anatomy. Xylem transports water and minerals from roots to leaves and is composed of vessels and tracheids, while phloem transports organic nutrients like sugars from leaves to other parts of the plant and is made up of sieve tubes and companion cells. What is the function of the root cap in plant anatomy? The root cap protects the delicate apical meristem as the root pushes through the soil and also secretes mucilage to ease movement through soil particles. Identify and describe the primary tissues found in a plant stem. Primary tissues in a plant stem include the epidermis (protective outer layer), cortex (storage and support), vascular tissues (xylem and phloem for transport), and pith (central parenchyma for storage). How do monocot and dicot leaf structures differ in plant anatomy? Monocot leaves typically have parallel venation, a uniform mesophyll, and scattered vascular bundles, whereas dicot leaves have reticulate (net-like) venation, differentiated palisade and spongy mesophyll, and vascular bundles arranged in a ring. Explain the role of the cambium in plant growth and anatomy. The cambium is a lateral meristem responsible for secondary growth, producing new xylem and phloem cells, which increase the thickness of stems and roots over time. What are stomata, and why are they important in plant anatomy? Stomata are tiny pores on the leaf surface surrounded by guard cells that regulate gas exchange and water vapor loss, playing a crucial role in photosynthesis and transpiration.
