- Structure: The heart has four chambers:
- Atria: The upper chambers (right and left atria) receive blood returning to the heart.
- Ventricles: The lower chambers (right and left ventricles) pump blood out of the heart.
- Valves: To ensure unidirectional flow, the heart contains four main valves:
 - Tricuspid valve
 - Pulmonary valve
 - Mitral (bicuspid) valve
 - Aortic valve

Blood Vessels

Blood vessels form a closed circulatory loop, comprising arteries, veins, and capillaries.

- Arteries: Carry oxygen-rich blood away from the heart to tissues.
- Veins: Return deoxygenated blood back to the heart.
- Capillaries: Microscopic vessels where exchange of gases, nutrients, and waste occurs between blood and tissues.

Blood

Blood is a specialized connective tissue composed of various components that serve vital functions.

- Components of blood:

The primary function of blood is to transport oxygen, nutrients, hormones, and waste products throughout the body, as well as helping to regulate body temperature and maintain pH balance. What are the main components of a blood packet used for medical purposes? A blood packet typically contains whole blood or specific components like packed red blood cells, plasma, and platelets, each separated for targeted medical treatments. How does the anatomy of blood vessels facilitate blood circulation? Blood vessels, including arteries, veins, and capillaries, are structured to efficiently carry blood: arteries have thick, muscular walls to withstand high pressure; veins have valves to prevent backflow; capillaries are thin-walled to allow exchange of substances.
